

SUMMARY OF THE FINDINGS OF MINOR RESEARCH PROJECT (MRP)

Title of the Project : Synthesis and characterization of Ti and Mn based metal oxide nanomaterial supercapacitor

UGC Reference No. : F.47-764/13 (WRO) Dated – 20th March 2014.

1. Name of Principal Investigator :- Dr. Devidas R. Bambole
2. Period of report from :- 20/03/2014 to 20/03/2016
3. Sanctioned Amount :- Rs. 65,000/-
4. Fund received :- Rs.35,000/-
5. Sanctioned letter received on dated :- 27/05/2014

The work on project entitled “Synthesis and characterization of Ti and Mn based metal oxide nanomaterial supercapacitor” was started with literature survey on supercapacitor based on the different electrode material such as nickel, cobalt, Mn, Zn, Mn etc. An electrode plays a very important role in the supercapacitor. Depending upon the electrode material used, the supercapacitors are divided into two categories: electrochemical double layer supercapacitor (EDLCs) and pseudocapacitor. In (EDLCs), the electrode material as have been used as SWNT, MWNT, reduce graphine oxide, porous carbon, etc., and the specific capacitance arises from the non-Faradaic charge storage mechanism between electrode and electrolyte interface.

In pseudocapacitor, the electrode materials that have been used as electrode is transition metal oxide, and the specific capacitance arises from Faradaic reaction at the electrode interface. The transition metal oxides such as RuO₂, Fe₃O₄, Co₃O₄,

MnO₂, Mn₃O₄, CeO₂, Fe₂O₃ etc., and the ternary metal such as oxide ternary such as MnCo₂O₄, NiCo₂O₄, ZnFe₂O₄, ZnCo₂O₄, CoFe₂O₄, CuFe₂O₄ and NiFe₂O₄ etc., has been widely studied and employed as promising electrode material for pseudocapacitors. Among these ternary metal oxides, the MnCo₂O₄ is the most explored potential candidate as the electrode material for supercapacitors. This is because of the MnCo₂O₄ shows the excellent electrochemical properties, natural abundance, cost effectiveness and environmental friendly in nature.

After completion of the literature survey, we have studied the reports on synthesized the Ti and Mn doped MnCo₂O₄ nanostructured material via different synthesis approaches. Furthermore, for comparison of specific capacitance and energy density electrodes synthesized via two different methods such as sol- gel and surfactant assisted hydrothermal methods, we have synthesized the MnCo₂O₄ via two different synthesis approaches sol-gel citrate method and TEA assisted hydrothermal method. The as-synthesized material was characterized using XRD, FESEM, FT-IR, UV-visible spectroscopy etc. The comparative electrochemical analysis of fabricated MnCo₂O₄ electrodes for supercapacitor application was carried out using cyclic voltammetry, galvanostatic charge discharge and impedance spectroscopy in 1M Na₂SO₄ electrolyte.

In conclusion, a simple sol- gel citrate and TEA- ethoxylate assisted hydrothermal methods have adopted for synthesis of nanostructure MnCo₂O₄. The XRD patterns reveal that the both the samples of MnCo₂O₄ exhibits the spinel FCC structure. From FE-SEM images, it revealed that both the samples of MnCo₂O₄ are nanostructured with typical morphology. The as-synthesized NiCo₂O₄ nanocrystals

has been successfully utilised as the electrode for supercapacitor. Cyclic voltammetry and galvanostatic charge discharge study showed that the C-MnCo₂O₄ (a sol-gel citrate synthesized MnCo₂O₄) and T-MnCo₂O₄ (TEA- assisted hydrothermal synthesized MnCo₂O₄) electrodes possesses the excellent electrochemical performance in 1M Na₂SO₄ electrolyte. The C-MnCo₂O₄ demonstrates the maximum specific capacitance of 42.5 Fg⁻¹ at 1mAcm⁻². Moreover, T-MnCo₂O₄ results maximum specific capacitance of 2014 Fg⁻¹ at 1 mA g⁻¹. An Electrochemical impedance spectroscopic investigation for the C-MnCo₂O₄ and T-MnCo₂O₄ electrodes is good agreement with the result obtained from cyclic voltammetry and galvanostatic charge discharge.

doi: 10.3389/fmats.2017.00021

Recently, our modern society demands the portable electronic devices such as mobile phones, laptops, smart watches, etc. Such devices demand light weight, flexible, and low-cost energy storage systems. Among different energy storage systems, supercapacitor has been considered as one of the most potential energy storage systems. This has several significant merits such as high power density, light weight, eco-friendly, etc. The electrode material is the important part of the supercapacitor. Recent studies have shown that there are many new advancement in electrode materials for supercapacitors. In this review, we focused on the recent advancements in the cobalt oxides, manganese oxides, and their composites as an electrode material for supercapacitor.

Keywords: hybrid supercapacitor, cobalt oxide, manganese oxide, specific capacitance, specific surface area

INTRODUCTION

Energy storage has an equal importance as energy production. To face the global challenges, recently, our modern society demands lightweight, flexible, inexpensive, and environmentally friendly energy storage systems (Meng et al., 2010; Chodankar et al., 2015). Battery and supercapacitor are the major energy storage devices. But, slow charge–discharge rate, short life cycles, and high weight of battery limit its applications in portable and wearable devices (Meng et al., 2010). At present, supercapacitors have been receiving a great attention, because of their important features such as high energy density, high power density, light weight, fast charging–discharging rate, secure operation, and long life span (Jayalakshmi and Balasubramanian, 2008; Chodankar et al., 2015). The supercapacitor is also called electrochemical capacitor. This is used in various applications such as hybrid vehicles, power backup, military services, and portable electronic devices like laptops, mobile phones, wrist watches, wearable devices, roll-up displays electronic papers, etc. (Lee et al., 2011; Wang et al., 2012).

CLASSIFICATION OF THE SUPERCAPACITOR

On the basis of charge storage mechanism and material used as the electrode, the supercapacitors are divided into two categories: electrochemical double layer supercapacitors (EDLCs) and pseudocapacitor (Jayalakshmi and Balasubramanian, 2008). In EDLCs, the specific capacitance arises from the non-Faradaic charge storage mechanism between electrode and electrolyte interface (Jayalakshmi and Balasubramanian, 2008; Wang et al., 2012). The materials that have been used as electrode

for EDLCs are porous carbon (Kang et al., 2015), SWNT (Liu et al., 2006), MWNT (Huang et al., 2014a), reduce graphine oxide (Zhang and Zhao, 2012), aerogel (Faraji and Ani, 2015), etc. In pseudocapacitor, the specific capacitance arises from Faradaic reaction at the electrode interface. The materials that have been studied as electrode for pseudocapacitors are transition metal oxides and conducting polymers (Wang et al., 2012).

In particular, the specific capacitance of the supercapacitors depends on the surface area and the pore size distribution of the electrode material. Compared with the transition metal oxides and conducting polymers, carbon and its different types have high surface area ($3.270 \text{ m}^2\text{g}^{-1}$) (Kang et al., 2015). However, this high surface area of carbon is not completely accessible for the electrolyte (Faraji and Ani, 2015). To overcome this shortcoming, the composites of carbon with transition metal oxides or conducting polymer have received great attention. These composite are also called hybrid materials. The use of hybrid material as an electrode in supercapacitors result in the third category of supercapacitors called hybrid supercapacitors. In hybrid supercapacitors, the specific capacitance arises from Faradic as well as non-Faradic charge storage mechanism at the electrode and electrolyte interface (Zhang et al., 2013; Pardieu et al., 2015).

PARAMETERS FOR SUPERCAPACITOR

The specific capacitance (C_s) (Fg^{-1}), energy density E (Wh kg^{-1}), power density P (kW kg^{-1}), and retention capacity or coulomb efficiency (η) are the crucial characteristics of the supercapacitor device. The (C_s) (Fg^{-1}) at the single electrode of the device is calculated given by,

$$C_s = \frac{1}{mV(V_c - V_a)} \int_{V_a}^{V_c} I(v) dV \quad (1)$$

where m is the mass (g cm^{-1}) deposited, $I(v)$ is the response current (mA) of the electrode material for unit area, V is the scan rate, $V_c - V_a$ is the operational potential window in (V), V_a anodic current, and V_c cathodic current. Energy density E (Wh kg^{-1}) and power density P (W kg^{-1}) of supercapacitor are calculated using following relations as,

$$E = \frac{0.5 \times C_s \times (V_{\max}^2 - V_{\min}^2)}{3.6} \quad (2)$$

$$P = \frac{E}{t_D} \quad (3)$$

where C_s is specific capacitance (Fg^{-1}), V_{\max} and V_{\min} are the maximum and minimum voltage achieved during charging and discharging process, respectively, in volt (V), and t_D is the discharging time (s) for a cycle of the supercapacitor. The retention of specific capacitance is calculated using the relation,

$$\eta = \frac{t_D}{t_C} \quad (4)$$

where t_C and t_D are the charge and discharge time (s), respectively, for a cycle of the supercapacitor (Wang et al., 2010; Dubal et al., 2012).

RECENT ADVANCES IN COBALT OXIDE SUPERCAPACITOR

The transition metal oxides have a great scientific significance. These are the basis of a variety of functional materials (Shinde et al., 2015). Among the various supercapacitor electrode materials, transition metal oxides offer high electronegativity, rich redox reactions, low cost, environmental friendliness, and excellent electrochemical performance. Different transition-metal oxides, such as IrO_2 , RuO_2 , Co_3O_4 , MnO_2 , Fe_2O_3 , SnO_2 ,

TABLE 1 | Co_3O_4 -based supercapacitors.

Sr. no.	Material	Method of synthesis	High surface area	Electrolyte	High Sp. capacitance	Retention	Year	Reference
1	Co_2O_3 on NiO substrate	Electrodeposition method		1 M KOH	345 Fg^{-1} at 20 mV s^{-1}	>50% after 200	2014	Sarma et al. (2014)
2	Co_3O_4 -decorated graphene	Microwave-assisted method	–	1 M KOH	600 Fg^{-1} at 0.7 A g^{-1}	94.5% after 5,000 cycles	2015	Kumar et al. (2015)
3	Pongam seed shell-derived activated carbon and cobalt oxide (Co_3O_4) nanocomposite	KOH activation method	164 $\text{m}^2 \text{g}^{-1}$	1 M KOH electrolyte	94 Fg^{-1} at 1 A g^{-1}	88% after 1,000 cycles	2015	Madhu et al. (2015)
4	$\text{Co}_3\text{O}_4/\text{NiCo}_2\text{O}_4$ double-shelled nanocages	The facile synthesis	–	2 M KOH	972 Fg^{-1} at a current density of 5 A g^{-1}	92.5% after 12,000 cycles	2015	Hu et al. (2015)
5	Synthesized titania nanotube cobalt (CoS) sulfide composite	Electrodeposition method	–	1 M Na_2SO_3	400 Fg^{-1} at charge density 5 mA cm^{-2}	>80% after 1,000 cycles	2015	Ray et al. (2015)
6	Co_3O_4 nanotubes	Chemical deposition method		6 ML^{-1} KOH	574 Fg^{-1} at 0.1 A g^{-1}	95% after 1,000 cycles	2010	Xu et al. (2010)
7	Ultrafine Co_3O_4 nanocrystal electrode	Laser ablation in liquid method	–		177 Fg^{-1} at scan rate 1 mV s^{-1}	100% after 20,000 cycles	2016	Liu et al. (2016)
8	Cobalt tungstate (CoWO_4)	Chemical precipitation reaction	–	0.2 M H_2SO_4	378 Fg^{-1} at scan rate 2 mV s^{-1}	95.5% after 4,000 cycles	2016	Adib et al. (2016)

NiO, etc., have been extensively studied as the electrode material for supercapacitor (Luo et al., 2014). Among these, RuO₂ has been identified as a dominant candidate because it has high theoretical specific capacitance (1,358 Fg⁻¹), high electrical conductivity (300 S cm⁻¹), and high electrochemical stability (Yu et al., 2013). However, the high cost and toxicity associated with the RuO₂ limits its commercial applications (Deng et al., 2014).

Furthermore, the cobalt oxides have received significant interest in recent years because of their low cost, non-toxic, easy synthesis, and environmental friendly nature. The cobalt oxides have high theoretical capacitance (CoO: 4.292 Fg⁻¹, Co₂O₄: 3.560 Fg⁻¹) (Cheng et al., 2010; He et al., 2012). Additionally, cobalt oxides show excellent electrochemical behavior in alkaline as well as organic electrolyte. These have the ability to interact with the ions of the electrolyte at the surface as well as through the bulk of the material (Vijayakumar et al., 2013). The features of cobalt oxides such as morphology, structures, and

dimension can be easily controlled *via* adjusting the preparative parameters such as, reaction temperature, reaction time, concentration of matrix solution, complexing agent, etc. (Wei et al., 2015a).

An optimized microstructure and controlled morphology of the material will enhance the specific surface area and pore size distribution, which facilitate the electrolyte ion transport in the material (Meher and Rao, 2011). Recently, many new approaches have been successfully in use to synthesize the meso and microporous nanostructure cobalt oxide materials such as hydrothermal method (Meher and Rao, 2011), chemical bath deposition method (Xu et al., 2010), hydrothermal precipitation method (Yu et al., 2009), solvothermal synthesis method (Yang et al., 2013), combustion synthesis method (Deng et al., 2014), microwave-assisted synthesis method (Vijayakumar et al., 2013), etc.

The specific capacitance of the cobalt oxide strongly depends on morphology, surface area, and pore size distribution. Recently,

8	Manganese oxide nanosheets/nanoporous gold	Galvanostatic electrodeposition	–	1 M Na ₂ SO ₄	775 Fg ⁻¹ at 1 A g ⁻¹	95% after 1,000 cycles	2015	Zeng et al. (2015)
9	MnO ₂ on graphene	Hydrothermal method	–	1 M Na ₂ SO ₄	315 Fg ⁻¹ at a current density of 0.2 A g ⁻¹	87% retained after 2,000 cycles at 3 A g ⁻¹	2013	Liu et al. (2013)
10	MnO ₂ nanosheets on flexible carbon fiber cloth	Flexible carbon fiber cloth: the direct carbonization of flax textile redox reaction between carbon and KMnO ₄	33.6 m ² g ⁻¹	0.1 M Na ₂ SO ₄	683.73 Fg ⁻¹ at 2 A g ⁻¹	94.5% retained after 2,000 cycles	2015	He and Chen (2015)

use of new synthesis approaches, surface modifying agents, complexing, and structure directing agent results in high-specific capacitance, which is equal the theoretical specific capacitance cobalt oxide. In this review paper, we have focused the recent advancements in the cobalt oxides and their composites as the electrode material. **Table 1** shows the preparation and supercapacitive performance of cobalt oxide and their composites based supercapacitors.

RECENT ADVANCES IN MANGANESE OXIDE SUPERCAPACITOR

Manganese (Mn) has different oxidation states. Out of these, the most stable oxidation states are Mn (II) and Mn (IV). The Mn (II) forms MnO, on the other hand, Mn (IV) forms MnO₂ and Mn₂O₃. The MnO₂ has α , β , γ , and δ -type polymorph (Chen et al., 2014; Salunkhe et al., 2015). The advantages of manganese-based metal oxides include low cost, low toxicity, natural abundance, and environmental friendly in nature (Sui et al., 2015; Wei et al., 2015b). In aqueous and organic electrolyte, the MnO, MnO₂, and Mn₂O₃ can form the different oxidation states. Thus, it results in the high-specific capacitance. The highest reported theoretical specific capacitance of MnO₂ is 1.370 Fg⁻¹ (Guo et al., 2015a; Wei et al., 2015b). However, the low electrical conductivity and large volume change during the charge–discharge process result in the unsatisfactory rate performance and cyclic stability. In consequence, this reduces the specific capacitance of the manganese oxides-based supercapacitors (Cabana et al., 2010; Chen et al., 2010). To overcome such hindrances, recently, the researchers have been executing many new strategies, such as use of carbon containing materials for increasing the electrical conductivity and adopt the volume buffers for relaxing internal stresses (Yao et al., 2008; Sui et al., 2015). Manganese oxides have been prepared by various synthesis methods, such as pulse laser deposition method (Xia et al., 2011), hydrothermal method (Zhang et al., 2014), electrochemical synthesis method (Jiang and Kucernak, 2002), redox deposition method (Bordjiba and Bélanger, 2009), successive hydrolysis–condensation method (Sawangphruk and Limtrakul, 2012), etc. Further, the detail

of MnO₂ synthesis and their supercapacitive performance are shown in **Table 2**.

CONCLUSION AND FUTURE PROSPECTIVE

Recently, cobalt- and manganese-based metal oxide as the electrode materials for supercapacitor have been receiving the great attention. From the recent reports, it has concluded that,

- (1) Advanced chemical method such as hydrothermal, pulse laser deposition, reverse microemulsion, microwave-assisted, etc., has been assisted to synthesize cobalt- and manganese-based metal oxide material.
- (2) The specific capacitance of the cobalt oxide- and manganese-based metal oxide supercapacitor strongly depends on morphology, surface area, and pore-size distribution.
- (3) In most of the reports, the composites of cobalt oxide or manganese oxide with carbon material, i.e., hybrid materials are used as an electrode for supercapacitor. Moreover, this results in high-specific capacitance.
- (4) In addition, the increase in conductivity of the cobalt oxide and manganese oxides is projected if this material and carbon material are combined. This makes the application of cobalt oxide and manganese oxides in high energy applications. As a result, the proposed material cobalt oxides and manganese oxide are a promising material for flexible, portable high-rate hybrid supercapacitor, and has plenty room for advancements.

Abstract

Herein present paper, the sol-gel citrate route for synthesis of crystalline MnCo_2O_4 nanosphers is reported. The as-synthesized nanocrystalline MnCo_2O_4 were characterized by means of X-ray diffraction (XRD), Field emission scanning electron microscopy (FE-SEM), Fourier transform infrared spectroscopy (FTIR) and Brunauer–Emmett–Teller (BET). The XRD analysis reveals the nanocrystalline nature of as-prepared MnCo_2O_4 nanocrystals. Electrochemical properties of nanocrystalline MnCo_2O_4 have been studied by cyclic voltammetry, Galvanostatic charge–discharge and electrochemical impedance spectroscopy, which showed the maximum specific capacitance of 42.5 F g^{-1} at current density 0.1 mAcm^{-2} . The synthesis method used in this study is promising for producing the nanocrystalline material for high performance supercapacitor electrode.

Keywords: Nanocrystalline, capacitor, capacitance.

I. INTRODUCTION

To meet the recent and future challenges in the modern society, the flexible, wearable, lightweight and low cost energy storage system has a very intense demand [1]. In this regards, the world has an ample expectation from the scientific community for finding new energy storage system that fulfils these requirements. Recently, supercapacitor or electrochemical capacitor (EC) is the emerging energy storage

systems are currently having intense demands. Supercapacitor is going to overcome the recent commercial energy storage like conventional capacitor and lead acid battery. Supercapacitor has many attractive features such as high power density, high energy density, lightweight, fast charging–discharging rate, a good shelf life, secure operation and long life span etc. [ii,iii]. The supercapacitor is used in various applications such as hybrid vehicles, military services and power backup, portable electronics like laptops, mobile phones, wrist watches, wearable devises, roll-up displays electronic papers, etc.[iv,v].

An electrode plays a very important role in the supercapacitor. Depending upon the electrode material used, the supercapacitors are divided into two categories: electrochemical double layer supercapacitor (EDLCs) and pseudocapacitor [vi]. In (EDLCs), the electrode material have been used as SWNT [vii], MWNT [viii], reduced graphine oxide [ix], porous carbon [x], etc., and the specific capacitance arises from the non-Faradaic charge storage mechanism between electrode and electrolyte interface. In pseudocapacitor, the electrode materials that have been used as electrode are transition metal oxides, and the specific capacitance arises from Faradaic reaction at the electrode interface [xi].

The transition metal oxides such as RuO_2 , Fe_3O_4 , Co_3O_4 , MnO_2 , Mn_3O_4 , CeO_2 , Fe_2O_3 etc., and the ternary metal such as MnCo_2O_4 , NiCo_2O_4 , ZnFe_2O_4 , ZnCo_2O_4 , CoFe_2O_4 ,

CuFe₂O₄ and NiFe₂O₄ etc., has been widely studied and employed as promising electrode material for pseudocapacitors [xii].

Among these ternary metal oxides, the MnCo₂O₄ is the most explored potential candidate in view point of electrode material for supercapacitor owing to its excellent electrochemical properties, natural abundance, cost effectiveness and environmentally compatible nature. In this context several researchers have reported the remarkable results. Sun *et al.* [xiii] have reported the hydrothermally synthesized MnCo₂O₄/C electrode material for water splitting and all state solid supercapacitor application with high specific capacitance of 846 mFcm⁻² at current density 20 μA cm⁻².

Further, Yaun *et al.* [xiv] have reported the one step hydrothermal route synthesis of MnCo₂O₄/reduced graphene oxide nanocomposites for supercapacitor with specific capacitance 334 Fg⁻¹ at current density 1 Ag⁻¹. Sahoo *et al.* [xv] have reported the one-step electrodeposition approach for the synthesis of MnCo₂O₄ and reported the specific capacitance of 290 Fg⁻¹ at scan rate 1 mVs⁻¹.

In the present report, we have synthesized the MnCo₂O₄ via sol-gel citrate method. The synthesized material was characterized using XRD, FE-SEM, FTIR, UV-visible spectroscopy, BET-BJH etc. The electrochemical investigations for supercapacitor application of fabricated MnCo₂O₄ electrode was carried out using cyclic voltammetry, galvanostatic charge discharge and impedance spectroscopy.

II. EXPERIMENTAL

A. MATERIALS AND METHOD

All reagents including KMnO₄, Co(NO₃)₆H₂O and citric acid (C₆H₈O₇) were used as starting material and purchased from Qualigen Sd. fine chemicals Ltd. India. The chemical reagents were of analytical grade and used as received.

B. Synthesis of crystalline MnCo₂O₄ nanosphere

Synthesis of nanocrystalline MnCo₂O₄ was carried out by sol-gel citrate method. Initially, the stoichiometric amount of KMnO₄ and Co(NO₃)₆H₂O with the molar ratio 1:2 were dissolved in methanol. This solution was stirred for 1 hr using a magnetic stirrer followed by vigorous stirring at 80°C on

the hot plate for 3 hrs, which results in highly viscous homogenous thick gel. This gel was further transferred to a pressure bomb. The pressure bomb was sealed and heated up to 120°C for 12h and subsequently cooled to room temperature. The obtained dried samples were further ground and calcined at 550°C up to 6 h using alumina crucible in furnace.

C. FABRICATION OF ELECTRODE

The nanocrystalline MnCo₂O₄ material was loaded on stainless steel substrate following the standard protocol used for supercapacitor measurement [xvi,xvii]. For this, the 75 weight % of active material, 15 weight % acetylene black as a conductive additive and 10 weight % Poly vinylidene fluoride (PVDF) as a binder were mixed and ground in mortar to have a homogenous mixture. This mixture was further dispersed in a dimethyl formamide (DMF) to form slurry. This slurry was coated on stainless steel (SS) substrate using doctor blade and dried at 60°C. The electrochemical studies such as cyclic voltammetry, galvanostatic charge discharge and impedance spectroscopy were performed using the CHI 6002C and CHI 604E electrochemical workstation forming an electrochemical cell comprising fabricated electrode as working electrode, platinum as counter electrode and Ag/AgCl as a reference electrode in 1 M Na₂SO₄ electrolyte.

D. CHARACTERIZATION

The structural properties and phase identification of the samples was done by Philips X-ray diffractometer (XRD) with filtered Cu-K_α radiation of wavelength λ = 0.1541874 nm. The morphology was determined by Field emission scanning electron microscopy (FE-SEM) (Model: JSM 6701F, JEOL, Japan). The Fourier transform infrared (FTIR) spectra were recorded using Bruker vertex 70 FTIR spectrometer. The UV-Visible investigation of the material was carried out by using Perkin-Elmer Lambda 750, USA.

III. RESULT AND DISCUSSIONS

A. XRD analysis

To understand the lattice parameter and average crystallite size of the as-synthesized MnCo₂O₄ samples, the X-ray diffraction (XRD) analysis was carried out. Fig. 1 shows the typical XRD pattern of as-synthesized MnCo₂O₄. From the XRD pattern, the sharp peaks appearing at two theta values 31°, 36.95°, 44.44°, 52.07°, 58.18°, 64.52°, 66.9° and 76.85°

can be assigned to (222), (311), (400), (422), (511), (440), (531) and (533) respectively, and are in well agreement to those of spinel fcc structure with space group $Fd\bar{3}m$, (227), [JCPDF 23-1237] [xviii,xix]. Further, no impurity peaks were found in the XRD pattern which indicates the formation of well crystalline $MnCo_2O_4$. The average crystallite size D was calculated using the Deby-Scherrer formula [xx] equation (1), where λ is the characteristic wavelength of Cu-K α radiation, β is the full width half maxima of the diffraction line at half the maximum intensity and θ is the Bragg diffraction angle. The average crystalline size for the $MnCo_2O_4$ was found to be 32 nm.

$$D = \frac{0.9\lambda}{\beta \times \cos \theta} \quad (1)$$

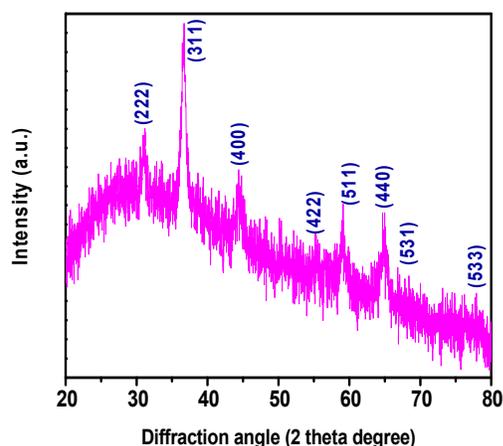

Fig. 1: XRD pattern of nanocrystalline $MnCo_2O_4$

B. FE-SEM analysis

The morphology of as-synthesized nanocrystalline $MnCo_2O_4$ was studied by FE-SEM analysis and the results are shown in Fig. 2. (a) and (b). From high magnification FESEM images (Fig 2(a)-(b)), it can be seen that the as-synthesized product consists of nearly spherical morphology. The nanospheres are formed in large numbers and are separated from each other. The average size of the nanospheres ranges from 29-42 nm which are in close agreement with those of XRD results.

The crystalline nature with spherical morphology of as-synthesized $MnCo_2O_4$ material demonstrated here may exhibit greater surface area and may contribute to electrolyte ion exchange which is one of the prime requirements of high energy storage supercapacitor electrode material.

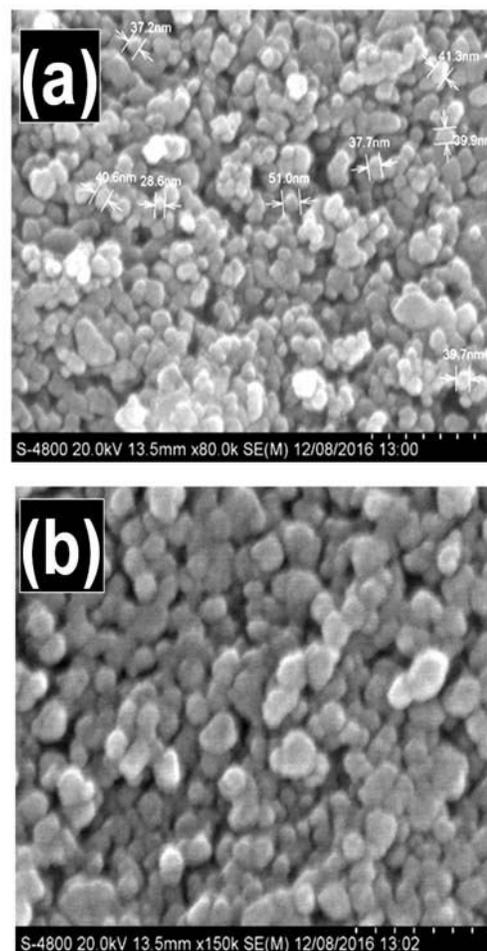

Fig. 2: FE-SEM micrograph of nanocrystalline $MnCo_2O_4$

C. FT-IR analysis

To analyze the bonding and chemical composition of the as synthesized nanocrystalline $MnCo_2O_4$, the Fourier transform infrared spectroscopy (FT-IR) analysis was carried. Fig. 3 shows the FT-IR spectrum of nanocrystalline $MnCo_2O_4$. The broad absorption peak appearing at 2922.59 cm^{-1} and 1609.7 cm^{-1} can be assigned to the O-H of adsorbed water molecule in $MnCo_2O_4$ [xxi,xxii]. The absorption band observed at 1348 cm^{-1} can be ascribed to NO_2 symmetrical stretching in the citrate molecule. The absorption bands at $750\text{--}600\text{ cm}^{-1}$ and $600\text{--}450\text{ cm}^{-1}$ are due to Mn-O stretching and bending vibrations in the nanocrystalline $MnCo_2O_4$ [xxiii]. The band at 720 cm^{-1} is due to NH_2 wagging from the citrate molecule [xxiv]. The band at 680 cm^{-1} can be attributed to the metal oxide bonding [xxv].

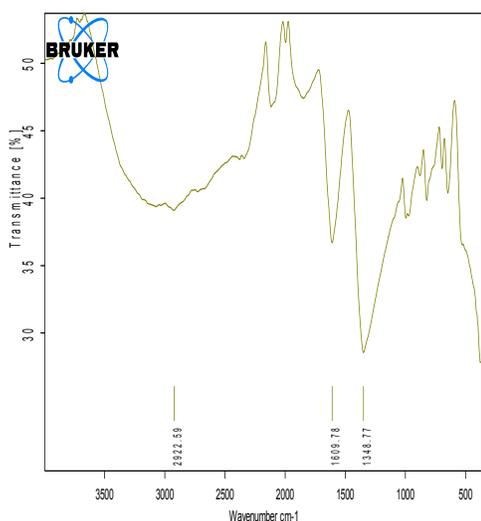

Fig. 3: FTIR spectrum of nanocrystalline MnCo_2O_4

D. UV- visible spectroscopy analysis

To investigate the optical band gap in the nanocrystalline MnCo_2O_4 , the optical study of the as-synthesized nanocrystalline MnCo_2O_4 was carried out by using UV-vis spectrophotometer in the wavelength ranges 350–950 nm. The variation in absorption intensity with different wavelengths of nanocrystalline MnCo_2O_4 is shown in Fig. 4 (a) and corresponding plot of $(\alpha h\nu)^2$ versus $(h\nu)$ shown in the Fig. 4 (b). The electronic structure and band gap strongly influences the electrochemical properties of the composite material. Fig. 4 (b) shows the strong absorption of nanocrystalline MnCo_2O_4 in the 220-250 cm^{-1} region. The plot $(\alpha h\nu)^2$ versus $(h\nu)$ (Fig. 4 (b)), which is linear at the absorption edge, further confirms that the material has a direct band gap. The extrapolations of straight line to the energy axis for zero absorption coefficient value give the band gap which was observed to be 4.91 eV. These values are comparable with the theoretical values previously reported in literature [xxvi].

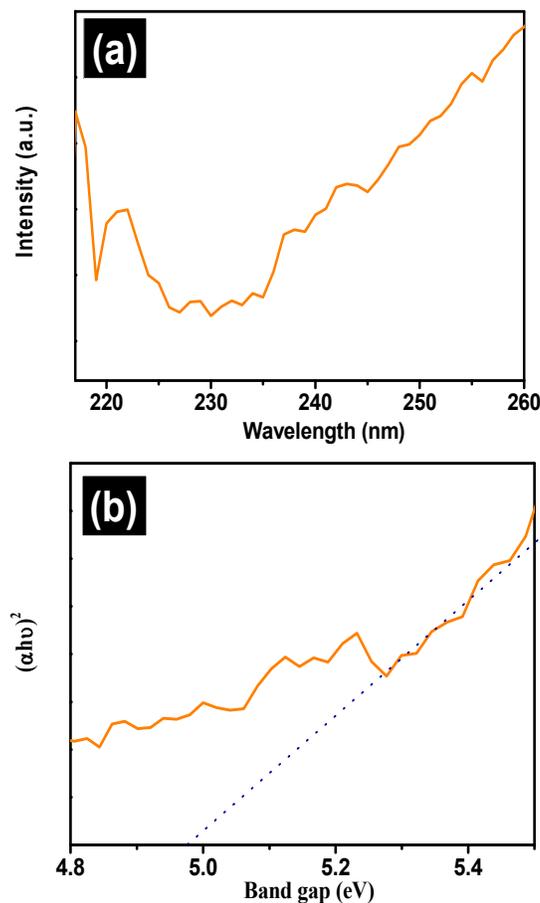

Fig. 4. (a) UV-Visible spectrum and (b) band gap of nanocrystalline MnCo_2O_4

E. BET surface area analysis

The Brunauer-Emmett-teller (BET) surface area analysis was carried out to explore the specific surface area of nanocrystalline MnCo_2O_4 . For this, the N_2 adsorption-desorption isotherm has been carried out. The corresponding results are demonstrated in Fig. 5. From figure, the isotherm with a distinct hysteresis loop in the range of 0 to 1 and at relative pressure P/P_0 can be clearly seen. The pore size distribution and pore volume of nanocrystalline MnCo_2O_4 are estimated using the Barrett-Joyner-Halenda (BJH) method. The pore size distribution of nanocrystalline MnCo_2O_4 at the amount of nitrogen absorbed at $P/P_0 = 0.98595$ are shown in inset of Fig. 5. The BET surface area and a corresponding pore volume of the nanocrystalline MnCo_2O_4 were found out to be $10.45 \text{ m}^2\text{g}^{-1}$ and $0.0213 \text{ cm}^3\text{g}^{-1}$ respectively.

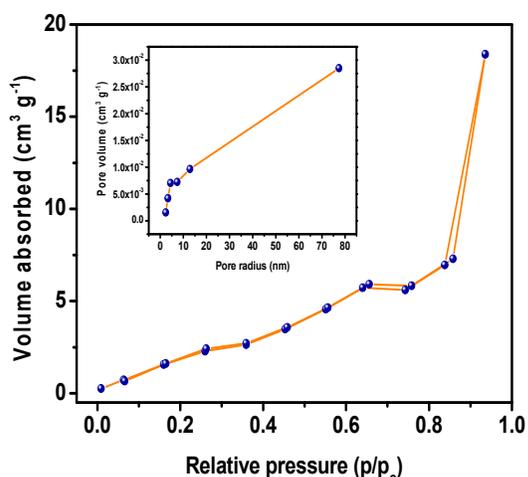

Fig. 5. N₂-adsorption-desorption isotherm and the inset shows the corresponding pore size distribution of nanocrystalline MnCo₂O₄

F. Electrochemical characterization analysis

To understand the electrochemical nature of nanocrystalline MnCo₂O₄ electrode, the cyclic voltammetry (CV), galvanostatic charge discharge (GCD) and Electrochemical impedance spectroscopy (EIS) has been carried out in 1 M Na₂SO₄ as electrolyte. The Fig. 6 (a) shows the CV curves of nanocrystalline MnCo₂O₄ in the different scan rates of 5 mVs⁻¹, 10 mVs⁻¹, 50 mVs⁻¹ and 100 mVs⁻¹ in the potential window 0 to 0.6V. The rectangular shape of CV reveals that the specific capacitance is originated from the redox reaction [xxvii]. From CV curves, the values of specific capacitance of nanocrystalline MnCo₂O₄ samples at different scan rate are calculated using the equation (2).

$$C_s = \frac{1}{mV(V_c - V_a)} \int_{V_a}^{V_c} I(V)dV \quad (2)$$

Where m is the mass in (gcm²) deposited, $I(v)$ is the response current in (mA) of the MgFe₂O₄ electrode for unit area, V is the scan rate, $(V_c - V_a)$ is the operational potential window in (V), V_a anodic current and V_c cathodic current.

Galvanostatic charge-discharge study of the electrodes of MnCo₂O₄ electrode at different current densities 0.1 to 0.5 mAcm⁻² has been studied using 1M Na₂SO₄ as electrolyte. Fig.6 (b) shows the galvanostatic charge discharge behaviour of the nanocrystalline MnCo₂O₄ electrode. The discharge specific capacitance was calculated by galvanostatic charge discharge curves using the equation (3). Additionally, the galvanostatic charge discharge

curve is used to measure the energy density and power density of the electrode material, an equation (4) and equation (5) were used to calculate the energy density E (W h Kg⁻¹) and power density P (W Kg⁻¹) respectively,

$$C_s = \frac{T_d \times I_d}{m \times \Delta V} \quad (3)$$

$$E = \frac{0.5 \times C_s \times (V_{\max}^2 - V_{\min}^2)}{3.6} \quad (4)$$

$$P = \frac{E \times 3600}{T_d} \quad (5)$$

Where C_s (Fg⁻¹) is the specific capacitance, I_d (A) is the current used for Galvanostatic discharge, T_d (s) discharging time, ΔV (V) potential window used for galvanostatic charge discharge and m (g) is the active mass of the electrode [xxviii]. From GCD, the maximum specific capacitance, energy density and power density of MnCo₂O₄ electrode at current density 0.1mAcm⁻² has obtained as 42.5 Fg⁻¹, 2.125W h Kg⁻¹ and 137.1kW Kg⁻¹, respectively. Adekunle *et. al.* [xxix] have reported the specific capacitance 11.76 Fg⁻¹ for the MWCNT-Co₃O₄/MWCNT asymmetric supercapacitor assembly in 1 M Na₂SO₄. In present reports, the specific capacitance for MnCo₂O₄ electrode at current density 0.1mA cm⁻¹ was found out to be 42.5 Fg⁻¹, which is high in comparison with the specific capacitance reported in the literature.

Further, the retention of specific capacitance of the MnCo₂O₄ electrode was examined at the current density 0.3 mAcm⁻² over 1000 cycles. Fig 7 (a) shows the curve for cycle number versus percentage capacity retention for MnCo₂O₄ electrode. From figure, it can be seen that the MnCo₂O₄ electrode shows the 95.23% retention of specific capacitance over 1000 cycles.

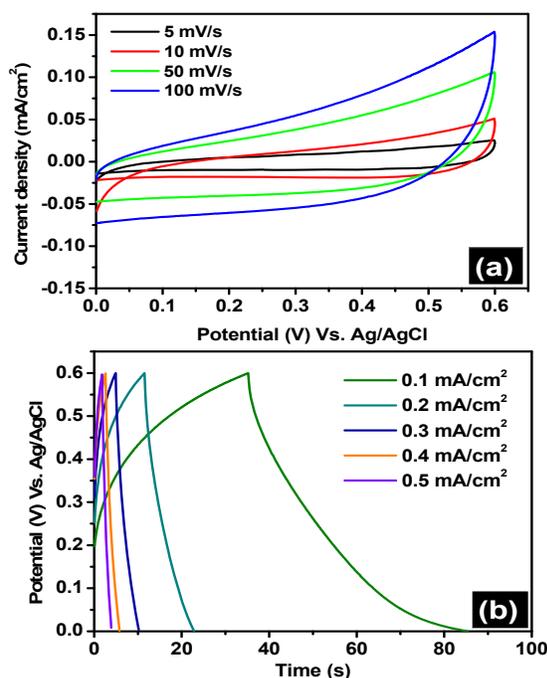

Fig. 6. (a) Cyclic voltammogram (CV), (b) Galvanostatic charge discharge (GCD) of nanocrystalline MnCo_2O_4

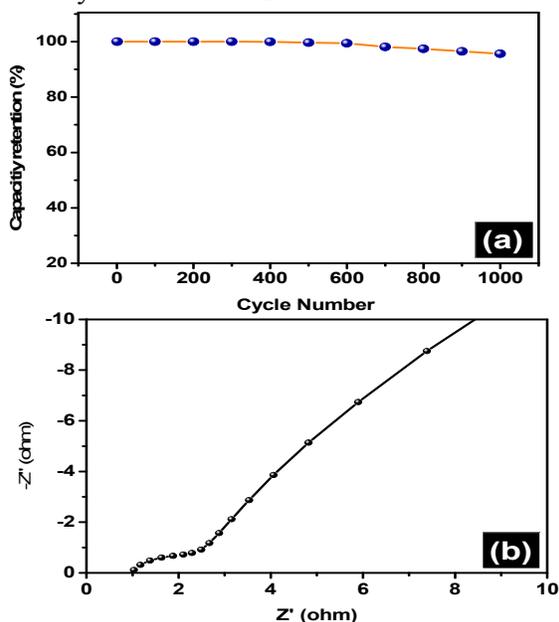

Fig. 7. (a) Capacity retention vs. cycle number at 0.3 mAcm^{-2} and (b) Nyquist plot of nanocrystalline MnCo_2O_4

The electrolyte resistance (R_s), the charge-transfer resistance (R_{ct}), the ion transport properties within the interface between the electrode and electrolyte was investigated with the help of electrochemical impedance spectroscopy (EIS). The ESI was investigated within the frequency range 1 Hz to 1 MHz at AC amplitude of 5 mV in 1 M Na_2SO_4 electrolyte.

The typical Nyquist plot for the MnCo_2O_4 nanostructure is shown in Fig. 7 (b). The high-frequency intercept of the semi-circle on the real axis yields the electrolyte resistance (R_s) or equivalent series resistance, and the diameter provides the charge-transfer resistance (R_{ct}) over the interface between the electrode and electrolyte [xxx]. The electrolyte resistance (R_s), the charge-transfer resistance (R_{ct}), of the nanostructure MnCo_2O_4 was found out to be $2 \Omega\text{cm}^{-2}$ and $1.24 \Omega\text{cm}^{-2}$ respectively. The low electrolyte resistance (R_s) and the charge-transfer resistance (R_{ct}) of the electrode material are mostly responsible for the result of ion exchange between electrode and electrolyte interface [xxx]. Fig. 8 (a) shows the Bode plot (Phase ($\Omega \text{ cm}^{-2}$) vs. Frequency (Hz)) of as-synthesized MnCo_2O_4 nanostructure.

At low frequency, the phase angle of the electrodes reached to the 45° implies the idea capacitive behavior of the electrode. The characteristic frequency f_0 of a phase angle of 45° is $\sim 100 \text{ Hz}$ for the MnCo_2O_4 nanostructure. The relaxation time constant t_0 , is calculated from the equation $t_0 = 1/f_0$, it was found out to be ~ 0.01 . Thus, ESI analysis of nanostructure MnCo_2O_4 is in good agreement with the results obtained from CV and GCD.

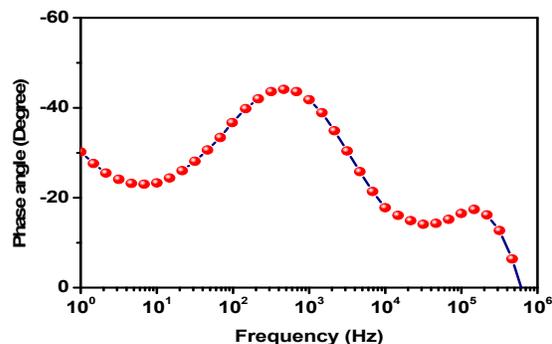

Fig. 8 (a) shows the Bode plot (Phase ($\Omega \text{ cm}^{-2}$) vs. Frequency (Hz)) for nanostructure MnCo_2O_4

IV. CONCLUSION

In conclusion, we have successfully synthesized the nanocrystalline MnCo_2O_4 via cost effective sol-gel citrate method. The nanocrystalline MnCo_2O_4 shows the excellent electrochemical performance in 1M Na_2SO_4 electrolyte. The electrochemical impedance spectroscopy reveals that the nanocrystalline MnCo_2O_4 is promising electrode material for high performance supercapacitor. Moreover, the present study demonstrates simple, cost effective sol-gel citrate method for fabrication

of uniform nanocrystalline MnCo_2O_4 with very high potential as the electrode for supercapacitor.

Abstract

In the present investigation, nanocrystalline spinel NiCo₂O₄ was synthesised by simple and cost effective sol-gel citrate method. Synthesized NiCo₂O₄ was characterized by using different characterization techniques. The electrochemical supercapacitive performance study shows that NiCo₂O₄ exhibits high specific capacitance of 342 Fg⁻¹ in 1 M Na₂SO₄ electrolyte with good stability. The further EIS analysis implies low ESR value with excellent frequency response of nanocrystalline NiCo₂O₄. Thus present study successfully conveys the applicability of easy and cost effective sol- gel citrate method for synthesis of nanocrystalline NiCo₂O₄ to be utilised for supercapacitor.

Keywords: supercapacitor, specific surface area, impedance spectroscopy, specific capacitance

1. INTRODUCTION

Due to the concerns about the depletion of fossil fuel, global warming issues and increasing demand of energy, the development of alternate energy storage resources with high power and energy capacity is of particular interest [1,2]. Among the various energy storage resources, supercapacitor, have attracted immense attention because many attractive properties, such as high energy density, fast charging-discharging and long cycle life [1]. The electrode material is an important part of supercapacitor. At present, the use of nanomaterials as the electrode of supercapacitors has attracted

great interest since they have shown higher power, energy densities and specific surface area than the respective bulk material [3]. The conductivity of the material directly influences the charge stored on the electrodes [4]. The binary transition metal oxides have a much higher electrical conductivity as compared to single transition metal oxides. The binary metal oxides such as NiCo_2O_4 , MnCo_2O_4 , ZnCo_2O_4 , CuFe_2O_4 , CoFe_2O_4 , ZnMn_2O_4 have been extensively studied for the electrode material in supercapacitor [5]. Among the binary metal oxides, NiCo_2O_4 is considered as a very promising electrode material for supercapacitor because of its good electrical conductivity, low cost, non toxicity and great flexibility in the structures and morphology [6,7].

This letter is aimed at presenting a more systematic report on the applicability of easy and cost effective sol- gel citrate method for synthesis of nanocrystalline NiCo_2O_4 to be utilised for supercapacitor. The specific capacitance of the supercapacitor can be enhanced by increasing the surface area of synthesized material. There are different methods of synthesis of NiCo_2O_4 [8,9], out of these different methods of synthesis of nanocrystalline NiCo_2O_4 , sol- gel citrate method is simple, cost effective and results in high surface area nanocrystals with desire morphology [10].

2. EXPERIMENTAL

Nanocrystalline NiCo_2O_4 was synthesised by using sol-gel citrate method. Nickel nitrate and cobalt nitrate were used as starting materials. A stoichiometric mixture of nitrates was mixed with citric acid and ethanol and stirred magnetically at 80°C for 3 h to obtain a homogenous mixture. The solution was further heated at the pressure vessel at about 130°C for 3h. The dried powder was then calcined at temperatures from 350°C to 750°C . Electrode was fabricated by dispersing the nanocrystalline powder of 95 weight % NiCo_2O_4 in dimethyl formamide as a solvent and 5 wt % Poly (Vinylidene fluoride) (PVDF) as binder, homogeneous gel formed deposited on stainless still as a substrate via bath deposition method. The electrochemical test of the sample was conducted using a three electrode system in 1 M Na_2SO_4 using a CHI 604e electrochemical workstation. The stainless still supported composite was directly used as working electrode with platinum plate counter electrode and Ag/AgCl as a reference electrode.

3. RESULT AND DISCUSSION

Fig 1(a) shows XRD pattern of nanocrystalline NiCo_2O_4 synthesised by sol- gel citrate method. It is seen that XRD pattern exhibits major peaks reflecting along the (311), other peaks corresponding to (111), (220), (400), (401), (422), (511) and (440) planes observed with a lower intensity. The XRD pattern of nanocrystalline NiCo_2O_4

is in good agreement with that of the standard pattern for NiCo₂O₄ (JCPDF File 20-0781) [11]. The result indicates that as prepared NiCo₂O₄ has spinel structure with polycrystalline in nature. The average crystalline size of NiCo₂O₄ is calculated by Deby-Scherrer formula [12] (1) and it is found to be 19 nm.

$$D = \frac{0.9 \lambda}{\beta \cos \theta} \quad (1)$$

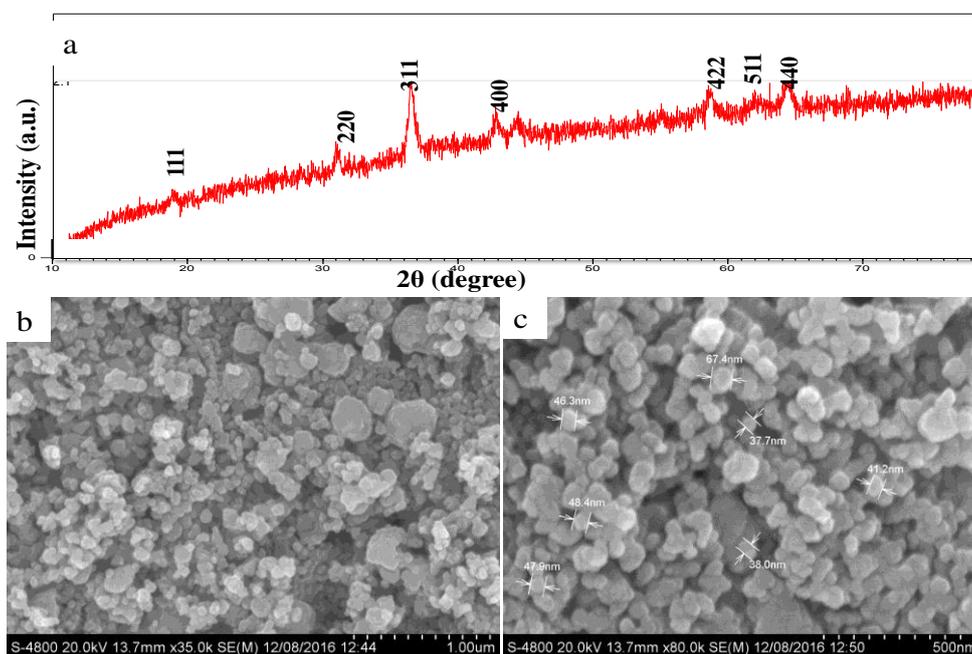

Fig.1. (a) XRD spectra, (b) and (c) FESEM micrograph

The morphology of NiCo₂O₄ is investigated by Field emission scanning electron microscopy (FE-SEM). Fig 1 (b) and (c) represent the FE-SEM micrographs of nanocrystalline NiCo₂O₄ at two different magnifications. From Fig 1 (b) and (c), it is seen that the random shaped aggregates and agglomeration clusters of NiCo₂O₄, the approximate size of which is about 38-68 nm. It is also seen that the size of nanocrystals are uniform, rough and porous with smaller particles suggesting high surface area.

The optical absorption spectrum in the range of 250-280 for NiCo₂O₄ is shown in Fig 2 (a). Inset of Fig 2 (a) shows the plot of photon energy ($h\nu$) versus $(\alpha h\nu)^2$, which is linear at the absorption edge conforms the material has a direct band gap. The optical band gap value of nanocrystalline NiCo₂O₄ estimated from classical relation equation (2) and it is found out to be 4.9 eV.

$$\alpha = \frac{A(h\nu - E_g)}{h\nu} \quad (2)$$

Thermogravimetric and differential thermal analysis (TG-DTA) in the temperature range between room temperature and 700°C were carried out on the nanocrystals of NiCo₂O₄ to investigate their thermal behaviour. The corresponding pattern is illustrated in Fig 2 (b). It is seen that, there is no much weight loss is observed with the increase in temperature. This is due to the material was calcined at 550°C and the contained impurities like moisture, structural water, nitrate, CO₂ etc. was already decomposed. The total weight loss is found to be 1.6%. This study confirms that the NiCo₂O₄ is thermally stable at higher temperatures and can be applied as the electrode material for supercapacitor at variable temperature applications.

The specific surface area of nanocrystalline NiCo₂O₄ has been measured through employing Brunauer-Emmett-teller (BET) method. To study surface area and porosity of nanocrystalline NiCo₂O₄ the N₂ adsorption-desorption isotherm has been carried out. The corresponding pattern is illustrated in Fig 2 (c) and (d). Fig 2 (c) shows the isotherm with a distinct hysteresis loop in the range of 0 to 1 and at relative pressure P/P_o . The observed hysteresis loop shifts to higher relative pressure on approaching $P/P_o = 1$, that suggests the hierarchical mesoporous structure of NiCo₂O₄. The pore size distribution and pore volume of NiCo₂O₄ are estimated using the Barrett-Joyner-Halenda (BJH) method. Fig 2 (d) shows the pore size distribution of NiCo₂O₄ at the amount of nitrogen absorbed at $P/P_o = 0.98595$. BET surface area of the NiCo₂O₄ is 22.011 m²/g and a corresponding pore volume is 0.0303 cm³/g. These results are in good agreement with the literature

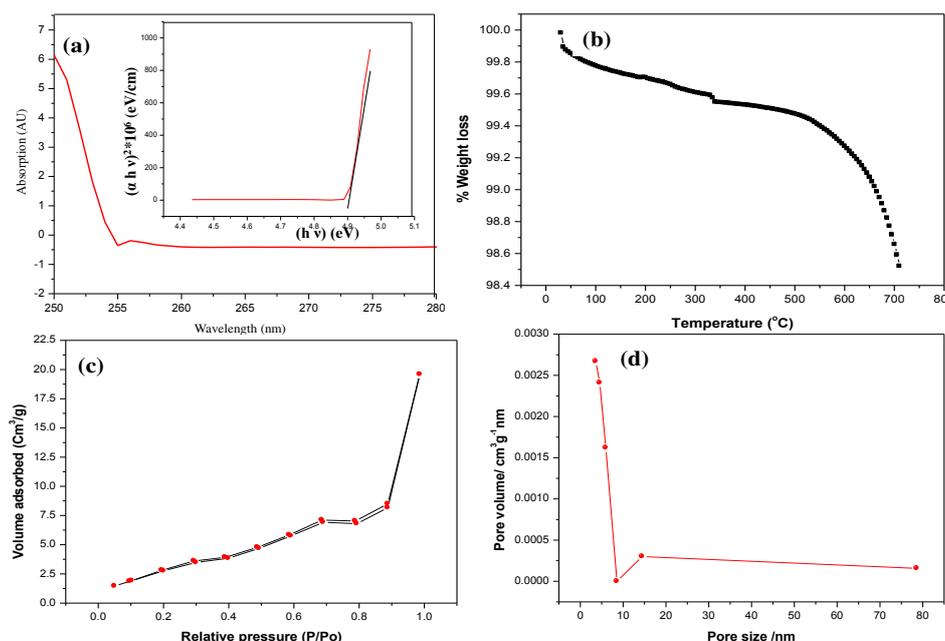

Fig 2 (a) UV- Visible spectra, inset shows the variation of photon energy ($h\nu$) vs $(\alpha h\nu)^2$, (b) Thermal analysis (c), N₂ adsorption desorption isotherm and (d) pore size distribution

To estimate the electrochemical behaviour of nanocrystalline NiCo₂O₄, Fig 3 (a) gives the cyclic voltammogram curves for nanocrystalline NiCo₂O₄ electrodes in the potential of -0.3 to 0.6V at scan rates 1, 10 and 100 mVs⁻¹ in 1M Na₂SO₄ electrolyte. Compared with the curves at different scan rates, all curves shows the pair of oxidation and reduction peaks, which indicates that the current potential response was potential dependant and pseudocapacitance mainly derived from redox reaction of nanocrystalline NiCo₂O₄ electrodes. It was found that the current responses as a function of scan rates and the slowly increased with the increase scan rate. This shows that the voltammogram currents are directly proportional to scan rates of CV. This indicates an ideally capacitive behaviour [13].

The NiCo₂O₄ electrode exhibits specific capacitance of 342 Fg⁻¹, 248 Fg⁻¹ and 13.3 Fg⁻¹ at 1 mVs⁻¹, 10 mVs⁻¹ and 100 mVs⁻¹ scan rates respectively. The maximum specific capacitance and energy density was calculated to be 342 Fg⁻¹ and 12.35 Wh Kg⁻¹ at scan rate 1mVs⁻¹. Fig 3(b) represents the variation of scan rate with the specific capacitance. As the scan rate increases, the specific capacitance decrease, which is distinctive for electrochemically active NiCo₂O₄. As shown in fig 3 (b) the specific capacitance decreases from 342 Fg⁻¹ to 13.3 Fg⁻¹. Such behaviour of supercapacitor is due to diffusion effects of protons within the electrodes and presence of inner active sites that cannot sustain the redox transition completely at higher scan rates[14].

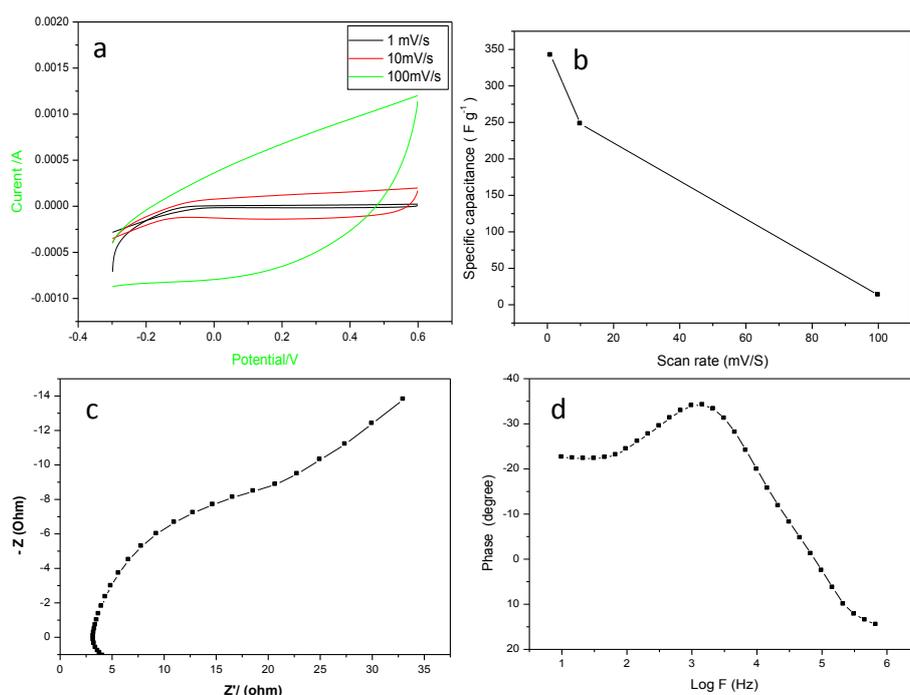

Fig 3 (a) cyclic voltammogram curve, (b) effect of scan rates on specific capacitance (c) Nyquist plot and (d) Bode plot

Impedance spectroscopic analysis of material was carried out in the frequency range 1Hz to 1MHz. Fig.3 (c) and (d) shows the Nyquist plot (real part vs. imaginary part of impedance) and Bode plots (frequency vs. phase angle) of nanocrystalline NiCo₂O₄ respectively. The intercept of the Nyquist plots to the real axis represents equivalent series resistance (R_s) which involves the electrolyte resistance, the intrinsic resistance of the electrode material and the contact resistance of active material to the current collector. The semicircle in the high frequency region gives the charge transfer resistance (R_{ct}), it is related to the internal resistance of the electrode and the double layer capacitance (C_{dl}). The charge transfer resistance (R_{ct}) was calculated by measuring the diameter of the semicircle. [15]. From fig 3 (c) equivalent series resistance (R_s) and charge transfer resistance (R_{ct}) of NiCo₂O₄ supercapacitor were found to be 4.7 Ω and 15.2 Ω respectively. The response-time data are calculated from Bode plot (*frequency Vs Phase*). Fig.3 (d) shows the Bode plot for electrode. These data follow the same trend as internal- resistance values. The ion-diffusion pathway through the layer of porous matrix is responsible for shorter response time [16]. The response time of NiCo₂O₄ is found to be less at a constant phase angle.

4. CONCLUSION

In summary, we have successfully synthesised nanocrystalline NiCo₂O₄ by cost effective sol-gel citrate method. BET surface area and corresponding pore volume of NiCo₂O₄ were found to be 22.011 m²/g and 0.0303 cm³/g respectively. The highest specific capacitance and energy density at scan rate 1 mVs⁻¹ were achieved to be 342 Fg⁻¹ and 12.35 W h Kg⁻¹ respectively. ESI study shows the low values of equivalent series resistance and charge transfer resistance are favourable for an increase in the value specific capacitance of NiCo₂O₄. Thus the results suggest that the sol-gel citrate method can serve as promising synthesis method for preparation of NiCo₂O₄ for high performance supercapacitor.
